

Salary Management System — Requirements Document

1. Goal

Build a web-based salary management system for ACME's HR team to replace spreadsheet-based salary management for approximately 10,000 employees across multiple countries.

The system should enable the HR Manager to manage current salary information and gain structured insights into organizational compensation.

2. Primary User

HR Manager — the single pre-authenticated persona responsible for managing employee and salary information and gaining insights into organizational compensation.

Authentication and RBAC are out of scope for the MVP and are documented as future production considerations.

3. MVP Scope

Employee Directory

- View a paginated list of employees.
- Search employees by name and employee ID.
- Filter employees by country, department, and designation.
- View employee details and current compensation.

Salary Management

- Create, view, and update current salary information.
- Store each employee's salary in their native/local currency.
- Support compensation attributes such as base, bonus, incentives, and last updated date.
- A current-state salary snapshot per employee is sufficient; salary history is not required.

Structured Dashboard Analytics

- Provide structured visual dashboards for compensation insights.
- Include KPI cards for key employee and salary metrics.
- Show country distributions.
- Show department-level salary/employee distributions.
- Normalize organization-wide salary analytics to USD using seeded FX exchange rates.

Multi-Currency & FX Normalization

- Store salaries in each employee's native/local currency.
- Maintain a seeded exchange-rate table with currency-to-USD rates.
- Use seeded FX rates to normalize salary totals and organization-wide analytics to USD.

Dataset

- Seed approximately 10,000 employees through a database seed script or migration using generated/fake data.
- Seed realistic countries, departments, designations, salaries, and supported currencies.

4. Optional Stretch Scope

AI Salary Q&A Chat

- Provide a natural-language interface for HR managers to ask questions about compensation data.
- Answers must be grounded in application salary data.
- Example questions: “What is the average salary of engineers in India?” and “Which department has the highest average salary?”

5. Non-Functional Requirements

- Support approximately 10,000 employees with responsive server-side search, filtering, and pagination.
- Use a relational database with appropriate indexing, constraints, and data integrity.
- Follow clean layered architecture: Controller → Service → Repository → Domain.
- Maintain meaningful unit/integration tests covering core business behavior using TDD.
- Avoid loading the full employee dataset into the frontend.

6. Explicitly Out of Scope

- Authentication and RBAC
- Pay-slip & Payroll processing
- Tax calculations and deductions
- Salary history
- Bulk CSV import and validation
- Attendance & Regularization Management
- Recruitment/onboarding workflows
- Performance management
- Audit trails

7. Success Criteria

- HR Manager can efficiently find employees and create/update current salary information.
- Salaries are maintained in native/local currencies and organization-wide analytics are normalized to USD using seeded FX rates.
- HR Manager can view meaningful structured compensation dashboards by country and department.
- The system performs responsive search, filtering, and pagination across approximately 10,000 seeded employees.
- Core business logic is covered by meaningful automated tests and implemented using clean, maintainable architecture.
